# Automata on Infinite Words

#### Definition of Büchi Automata

Let  $\Sigma = \{a, b, \ldots\}$  be a finite alphabet.

A non-deterministic Büchi automaton (NBA) over  $\Sigma$  is a tuple  $A = \langle S, I, T, F \rangle$ , where:

- S is a finite set of states,
- $I \subseteq S$  is a set of *initial states*,
- $T \subseteq S \times \Sigma \times S$  is a transition relation,
- $F \subseteq S$  is a set of *final states*.

## **Acceptance Condition**

A *run* of a Büchi automaton is defined over an infinite word  $w: \alpha_1\alpha_2...$  as an infinite sequence of states  $\pi: s_0s_1s_2...$  such that:

- $s_0 \in I$  and
- $(s_i, \alpha_{i+1}, s_{i+1}) \in T$ , for all  $i \in \mathbb{N}$ .

$$\inf(\pi) = \{s \mid s \text{ appears infinitely often on } \pi\}$$

Run  $\pi$  of A is said to be *accepting* iff  $\inf(\pi) \cap F \neq \emptyset$ .

The language of A, denoted  $\mathcal{L}(A)$ , is the set of all words accepted by A.

A language  $L \subseteq \Sigma^{\omega}$  is recognizable if there exists a Büchi automaton A such that  $L = \mathcal{L}(A)$ .

## Examples

Let  $\Sigma = \{0, 1\}$ . Define Büchi automata for the following languages:

- 1.  $L = \{ \alpha \in \Sigma^{\omega} \mid 0 \text{ occurs in } \alpha \text{ exactly once} \}$
- 2.  $L = \{ \alpha \in \Sigma^{\omega} \mid \text{after each } 0 \text{ in } \alpha \text{ there is } 1 \}$
- 3.  $L = \{ \alpha \in \Sigma^{\omega} \mid \alpha \text{ contains finitely many 1's} \}$
- 4.  $L = (01)^* \Sigma^{\omega}$
- 5.  $L = \{ \alpha \in \Sigma^{\omega} \mid 0 \text{ occurs on all even positions in } \alpha \}$

#### The Büchi Characterization Theorems

**Lemma 1** If  $L \subseteq \Sigma^*$  is a rational language, there exists a DFA  $A = \langle S, \{s_0\}, T, \{f\} \rangle$  such that  $s_0$  has no incoming transitions, f has no outgoing transitions, and  $L = \mathcal{L}(A)$ .

**Theorem 1** Let  $W, V \subseteq \Sigma^*$  be rational languages. Then the language  $V \cdot W^{\omega}$  is Büchi recognizable.

Is it possible that, for some non-rational language  $W \subseteq \Sigma^*$ ,  $W^{\omega}$  is Büchi recognizable?

#### First Büchi Characterization Theorem

Let  $A = \langle S, I, T, F \rangle$  be a Büchi automaton and  $s, s' \in S$  be two states.

Let 
$$W_{s,s'} = \{ w \in \Sigma^* \mid s \xrightarrow{w} s' \}.$$

The language  $W_{s,s'} \subseteq \Sigma^*$  is rational, for any  $s, s' \in S$ .

**Theorem 2** An  $\omega$ -language  $L \subseteq \Sigma^{\omega}$  is Büchi recognizable iff L is a finite union of  $\omega$ -languages  $V \cdot W^{\omega}$ , where  $V, W \subseteq \Sigma^*$  are rational languages.

"
$$\Rightarrow$$
"  $L = \bigcup_{s \in I, s' \in F} W_{s,s'} \cdot W_{s',s'}^{\omega}$ 

#### Second Büchi Characterization Theorem

**Theorem 3** An  $\omega$ -language  $L \subseteq \Sigma^{\omega}$  is Büchi recognizable iff L is a finite union of  $\omega$ -languages  $V \cdot W^{\omega}$ , where  $V, W \subseteq \Sigma^*$  are rational languages such that  $W \cdot W \subseteq W$ .

"\Rightarrow" 
$$\mathcal{L}(A) = \bigcup_{s \in I, s' \in F} W_{s,s'} W_{s',s'}^{\omega}$$
 and  $W_{s',s'} \cdot W_{s',s'} \subseteq W_{s',s'}$  for all  $s' \in F$ 

Corollary 1 Any non-empty Büchi-recognizable language contains an ultimately periodic word of the form uvvv....

## Closure Properties

Closure under union and projection are like in the finite automata case.

Intersection is a bit special.

Complementation of non-deterministic Büchi automata is a complex result.

Deterministic Büchi automata are not closed under complement.

#### Closure under Intersection

Let 
$$A_1 = \langle S_1, I_1, T_1, F_1 \rangle$$
 and  $A_2 = \langle S_2, I_2, T_2, F_2 \rangle$ 

Build  $A_{\cap} = \langle S, I, T, F \rangle$ :

- $S = S_1 \times S_2 \times \{1, 2, 3\},$
- $\bullet \ I = I_1 \times I_2 \times \{1\},$
- the definition of T is the following:
  - $-((s_1, s'_1, 1), a, (s_2, s'_2, 1)) \in T \text{ iff } (s_i, a, s'_i) \in T_i, i = 1, 2 \text{ and } s_1 \notin F_1$   $-((s_1, s'_1, 1), a, (s_2, s'_2, 2)) \in T \text{ iff } (s_i, a, s'_i) \in T_i, i = 1, 2 \text{ and } s_1 \in F_1$   $-((s_1, s'_1, 2), a, (s_2, s'_2, 2)) \in T \text{ iff } (s_i, a, s'_i) \in T_i, i = 1, 2 \text{ and } s'_1 \notin F_2$   $-((s_1, s'_1, 2), a, (s_2, s'_2, 3)) \in T \text{ iff } (s_i, a, s'_i) \in T_i, i = 1, 2 \text{ and } s'_1 \in F_2$   $-((s_1, s'_1, 3), a, (s_2, s'_2, 1)) \in T \text{ iff } (s_i, a, s'_i) \in T_i, i = 1, 2$
- $\bullet \ F = S_1 \times S_2 \times \{3\}$

## The Emptiness Problem

**Theorem 4** Given a Büchi automaton A,  $\mathcal{L}(A) \neq \emptyset$  iff there exist  $u, v \in \Sigma^*$ ,  $|u|, |v| \leq ||A||$ , such that  $uv^{\omega} \in \mathcal{L}(A)$ .

In practical terms, A is non-empty iff there exists a state s which is reachable both from an initial state and from itself.

**Q**: Is the membership problem decidable for Büchi automata?

#### Deterministic Büchi Automata

 $\omega$ -languages recognized by NBA  $\supset \omega$ -languages recognized by DBA

**Q**: Why classical subset construction does not work for Büchi automata?

Let 
$$A = \langle S, I, T, F \rangle$$
 and  $A_d = \langle 2^S, \{I\}, T_d, \{Q \mid Q \cap F \neq \emptyset\} \rangle$ .

Let  $u_0u_1u_2\ldots\in\mathcal{L}(A)$  be an infinite word. In  $A_d$  this gives:

$$I \xrightarrow{u_0} Q_1 \xrightarrow{u_1} Q_2 \xrightarrow{u_2} \dots$$

where each  $Q_i \cap F$ . However this does not necessarily correspond to an accepting path in A!

#### Deterministic Büchi Automata

Let  $W \subseteq \Sigma^*$ . Define  $\overrightarrow{W} = \{ \alpha \in \Sigma^\omega \mid \alpha(0, n) \in W \text{ for infinitely many } n \}$ 

**Theorem 5** A language  $L \subseteq \Sigma^{\omega}$  is recognizable by a deterministic Büchi automaton iff there exists a rational language  $W \subseteq \Sigma^*$  such that  $L = \overrightarrow{W}$ .

If  $L = \mathcal{L}(A)$  then  $W = \mathcal{L}(A')$  where A' is the DFA with the same definition as A, and with the finite acceptance condition.

#### Deterministic Büchi Automata

**Theorem 6** There exists a Büchi recognizable language that can be recognized by no deterministic Büchi automaton.

$$\Sigma = \{a, b\} \text{ and } L = \{\alpha \in \Sigma^{\omega} \mid \#_a(\alpha) < \infty\} = \Sigma^* b^{\omega}.$$

Suppose  $L = \overrightarrow{W}$  for some  $W \subseteq \Sigma^*$ .

$$b^{\omega} \in L \Rightarrow b^{n_1} \in W$$

$$b^{n_1}ab^{\omega} \in L \Rightarrow b^{n_1}ab^{n_2} \in W$$

• • •

 $b^{n_1}ab^{n_2}a\ldots\in\overrightarrow{W}=L$ , contradiction.

## Deterministic Büchi Automata are not closed under complement

**Theorem 7** There exists a DBA A such that no DBA recognizes the language  $\Sigma^{\omega} \setminus \mathcal{L}(A)$ .

$$\Sigma = \{a, b\} \text{ and } L = \{\alpha \in \Sigma^{\omega} \mid \#_a(\alpha) < \infty\} = \Sigma^* b^{\omega}.$$

Let  $V = \Sigma^* a$ . There exists a DFA A such that  $\mathcal{L}(A) = V$ .

There exists a deterministic Büchi automaton B such that  $\mathcal{L}(A) = \overrightarrow{V}$ 

But  $\Sigma^{\omega} \setminus \overrightarrow{V} = L$  which cannot be recognized by any DBA.

#### Büchi Automata and S1S

Let  $\Sigma = \{a, b, \ldots\}$  be a finite alphabet.

Any finite word  $w \in \Sigma^*$  induces the *infinite* sets  $p_a = \{p \mid w(p) = a\}$ .

- $x \le y : x$  is less than y,
- S(x) = y : y is the successor of x,
- $p_a(x)$ : a occurs at position x in w

Remember that  $\leq$  and S can be defined one from another.

#### Problem Statement

Let 
$$\mathcal{L}(\varphi) = \{ w \mid \mathfrak{m}_w \models \varphi \}$$

A language  $L \subseteq \Sigma^*$  is said to be S1S-*definable* iff there exists a S1S formula  $\varphi$  such that  $L = \mathcal{L}(\varphi)$ .

- 1. Given a Büchi automaton A build an S1S formula  $\varphi_A$  such that  $\mathcal{L}(A) = \mathcal{L}(\varphi)$
- 2. Given an S1S formula  $\varphi$  build a Büchi automaton  $A_{\varphi}$  such that  $\mathcal{L}(A) = \mathcal{L}(\varphi)$

The Büchi recognizable and S1S-definable languages coincide

#### From Automata to Formulae

Let  $A = \langle S, I, T, F \rangle$  with  $S = \{s_1, ..., s_p\}$ , and  $\Sigma = \{0, 1\}^m$ .

Build  $\Phi_A(X_1,\ldots,X_m)$  such that  $\forall w \in \Sigma^*$  .  $w \in \mathcal{L}(A) \iff w \models \Phi_A$ 

$$\Phi_A(X_1,\ldots,X_m) = \exists Y_1\ldots\exists Y_p\ .\ \Phi_S(\vec{Y})\land\Phi_I(\vec{Y})\land\Phi_T(\vec{Y},\vec{X})\land\Phi_F(\vec{Y})$$

$$\Phi_F(\vec{Y}) = \forall x \exists y \ . \ x \le y \land x \ne y \land \bigvee_{s_i \in F} Y_i(y)$$

## Consequences

**Theorem 8** A language  $L \subseteq \Sigma^{\omega}$  is definable in S1S iff it is Büchi recognizable.

Corollary 2 The SAT problem for S1S is decidable.

**Lemma 2** Any S1S formula  $\phi(X_1, \ldots, X_m)$  is equivalent to an S1S formula of the form  $\exists Y_1 \ldots \exists Y_p : \varphi$ , where  $\varphi$  does not contain other set variables than  $X_1, \ldots, X_m, Y_1, \ldots, Y_p$ .

## Müller and Rabin Word Automata

#### Müller Automata

Let  $\Sigma = \{a, b, \ldots\}$  be a finite alphabet.

**Definition 1** A Müller automaton over  $\Sigma$  is  $A = \langle S, s_0, T, \mathcal{F} \rangle$ , where:

- S is the finite set of states
- $s_0 \in S$  is the initial state
- $T: S \times \Sigma \mapsto S$  is the transition table
- $\mathcal{F} \subseteq 2^S$  is the set of accepting sets

Notice that Müller automata are deterministic and complete by definition.

## **Acceptance Condition**

A *run* of a Müller automaton is defined over an infinite word  $w: \alpha_1\alpha_2...$  as an infinite sequence of states  $\pi: s_0s_1s_2...$  such that:

•  $T(s_i, \alpha_{i+1}) = s_{i+1}$ , for all  $i \in \mathbb{N}$ .

Let  $\inf(\pi) = \{s \mid s \text{ appears infinitely often on } \pi\}.$ 

Run  $\pi$  of A is said to be accepting iff  $\inf(\pi) \in \mathcal{F}$ .

 $L \subseteq \Sigma^{\omega}$  is *Müller-recognizable* iff there exists a MA A such that  $L = \mathcal{L}(A)$ .

#### **Exercise**

Let  $\Sigma = \{a, b\}$  and  $A = \langle S, s_0, T, \mathcal{F} \rangle$ , where:

- $S = \{s_0, s_1\},$
- $T(s_0, a) = s_0$ ,  $T(s_0, b) = s_1$ ,  $T(s_1, a) = s_0$  and  $T(s_1, b) = s_1$ ,
- $\mathcal{F} = \{\{s_0, s_1\}\}$

What is  $\mathcal{L}(A)$ ? What if A was Büchi with  $F = \{s_0, s_1\}$ ?

#### Deterministic Büchi $\subseteq$ Müller

**Theorem 9** For each deterministic Büchi automaton A there exists a Müller automaton B such that  $\mathcal{L}(A) = \mathcal{L}(B)$ 

Let  $A = \langle S, \{s_0\}, T, F \rangle$  be a deterministic Büchi automaton.

Define  $B = \langle S, s_0, T, \{G \in 2^S \mid G \cap F \neq \emptyset\} \rangle$ 

## $M\ddot{u}$ ller $\subseteq$ Non-deterministic Büchi

**Theorem 10** For each Müller automaton A there exists a non-deterministic Büchi automaton B such that  $\mathcal{L}(A) = \mathcal{L}(B)$ .

Let  $A = (S, s_0, T, \mathcal{F})$  be a Müller automaton, with  $\mathcal{F} = \{F_1, \dots, F_n\}$ . Then B simulates A and guesses the accepting set  $F_i$ .

We introduce finite memory to accumulate  $F_i$  states. The Büchi automaton guesses when all the states outside  $F_i$  are finished.

When the memory is full we reset it to  $\emptyset$ , to ensure that we see  $F_i$  states again and again.

## Müller ⊆ Non-deterministic Büchi

Define the Büchi automaton  $B = (S_B, s_0, T_B, F_B)$  where:

- $S_B = S \cup (S \times 2^S \times \{1, \dots, n\})$
- $F_B = \{(s, \emptyset, i) \mid s \in S, i \in \{1, \dots, n\}\}$
- $T_B$  is defined as follows:
  - $-(s, \alpha, t) \in T_B$  and  $(s, \alpha, (t, \emptyset, i)) \in T_B$  if  $T(s, \alpha) = t$
  - $-((s,Q,i),\alpha,(t,Q\cup\{t\},i))\in T_B \text{ if } T(s,\alpha)=t \text{ and } Q\cup\{t\}\subset F_i$
  - $-((s,Q,i),\alpha,(t,\emptyset,i)) \in T_B \text{ if } T(s,\alpha) = t \text{ and } Q \cup \{t\} = F_i$

Now we prove that  $\mathcal{L}(A) = \mathcal{L}(B)$ .

## Closure Properties

**Theorem 11** The class of Müller-recognizable languages is closed under union, intersection and complement.

Let  $A = \langle S, s_0, T, \mathcal{F} \rangle$  be a Müller automaton.

Define  $B = \langle S, s_0, T, 2^S \setminus \mathcal{F} \rangle$ .

We have  $\mathcal{L}(B) = \Sigma^{\omega} \setminus \mathcal{L}(A)$ .

## Closure Properties

Let  $A_i = \langle S_i, s_{0,i}, T_i, \mathcal{F}_i \rangle$ , i = 1, 2 be Müller automata.

Define  $B = \langle S, s_0, T, \mathcal{F} \rangle$  where:

- $\bullet \ S = S_1 \times S_2,$
- $s_0 = \langle s_{0,1}, s_{0,2} \rangle$ ,
- $T(\langle s_1, s_2 \rangle, a) = \langle T(s_1, a), T(s_2, a) \rangle$
- $\mathcal{F} = \{\{\langle s_1, s_1' \rangle, \dots, \langle s_k, s_k' \rangle\} \mid \{s_1, \dots, s_k\} \in \mathcal{F}_1 \text{ or } \{s_1', \dots, s_k'\} \in \mathcal{F}_2\}$

We have  $\mathcal{L}(B) = \mathcal{L}(A_1) \cup \mathcal{L}(A_2)$ .

For intersection it is enough to set

$$\mathcal{F} = \{ \{ \langle s_1, s_1' \rangle, \dots, \langle s_k, s_k' \rangle \} \mid \{s_1, \dots, s_k\} \in \mathcal{F}_1 \text{ and } \{s_1', \dots, s_k'\} \in \mathcal{F}_2 \}$$

## Characterization of Müller-recognizable languages

A language  $L \subseteq \Sigma^{\omega}$  is Müller-recognizable iff L is a Boolean combination of sets  $\overrightarrow{W}$ ,  $W \subseteq \Sigma^*$ , i.e.  $L = \bigcup_i \left( \bigcap_j \overrightarrow{W_{ij}} \cap \bigcap_k (\Sigma^{\omega} \setminus \overrightarrow{W_{ik}}) \right)$ .

"\( = \)" Any set  $\overrightarrow{W}_{ij}$  is recognized by a deterministic Büchi automaton, hence also by a Müller automaton.

" $\Rightarrow$ " Let  $A = \langle S, s_0, T, \mathcal{F} \rangle$  be a Müller automaton recognizing L.

Let 
$$A_q = \langle S, s_0, T, \{q\} \rangle$$
,  $q \in S$ , and  $W_q = \mathcal{L}(A_q)$ .

$$L = \bigcup_{Q \in \mathcal{F}} \left( \bigcap_{q \in Q} \overrightarrow{W_q} \cap \bigcap_{q \in S \setminus Q} (\Sigma^{\omega} \setminus \overrightarrow{W_q}) \right)$$

#### Rabin Word Automata

Let  $\Sigma = \{a, b, \ldots\}$  be a finite alphabet.

**Definition 2** A Rabin automaton over  $\Sigma$  is  $A = \langle S, s_0, T, \Omega \rangle$ , where:

- S is the finite set of states
- $s_0 \in S$  is the initial state
- $T: S \times \Sigma \mapsto S$  is the transition table
- $\Omega = \{\langle N_1, P_1 \rangle, \dots, \langle N_k, P_k \rangle\}$  is the set of accepting pairs,  $N_i, P_i \subseteq S$ .

Run  $\pi$  of A is said to be accepting iff

$$\inf(\pi) \cap N_i = \emptyset \text{ and } \inf(\pi) \cap P_i \neq \emptyset$$

for some  $1 \leq i \leq k$ .

## The Streett acceptance condition

The Rabin acceptance condition is of the form:

$$\bigvee_{1 \le i \le k} inf(\pi) \cap N_i = \emptyset \land inf(\pi) \cap P_i \ne \emptyset$$

The Streett acceptance condition is the negation:

$$\bigwedge_{1 \le i \le k} inf(\pi) \cap N_i \neq \emptyset \rightarrow inf(\pi) \cap P_i \neq \emptyset$$

#### From Rabin to Müller

Given a Rabin automaton  $A = \langle S, s_0, T, \Omega \rangle$ , there exists a Müller automaton B such that  $\mathcal{L}(A) = \mathcal{L}(B)$ 

Let 
$$\Omega = \{\langle N_1, P_1 \rangle, \dots, \langle N_k, P_k \rangle\}.$$

Let 
$$A_i = \langle S, s_0, T, P_i \rangle$$
, and  $B_i = \langle S, s_0, T, N_i \rangle$ .

$$\mathcal{L}(A) = \bigcup_{i=1}^{k} \left( \overline{\mathcal{L}(A_i)} \cap (\Sigma^{\omega} \setminus \overline{\mathcal{L}(B_i)}) \right)$$

## From Rabin to Müller (2)

Given a Rabin automaton  $A = \langle S, s_0, T, \Omega \rangle$ , such that

$$\Omega = \{\langle N_1, P_1 \rangle, \dots, \langle N_k, P_k \rangle\}$$

let  $B = \langle S, s_0, T, \mathcal{F} \rangle$  be the Müller automaton, where

$$\mathcal{F} = \{ F \subseteq S \mid F \cap N_i = \emptyset \text{ and } F \cap P_i \neq \emptyset \text{ for some } 1 \leq i \leq k \}$$

#### From Müller to Rabin

Given a Müller automaton  $A = \langle S, s_0, T, \mathcal{F} \rangle$ , there exists a Rabin automaton B such that  $\mathcal{L}(A) = \mathcal{L}(B)$ 

Let 
$$\mathcal{F} = \{Q_1, \dots, Q_k\}$$

Let  $B = \langle S', s'_0, T', \Omega' \rangle$  where:

- $S' = 2^{Q_1} \times \ldots \times 2^{Q_k} \times S$
- $s_0' = \langle \emptyset, \dots, \emptyset, s_0 \rangle$

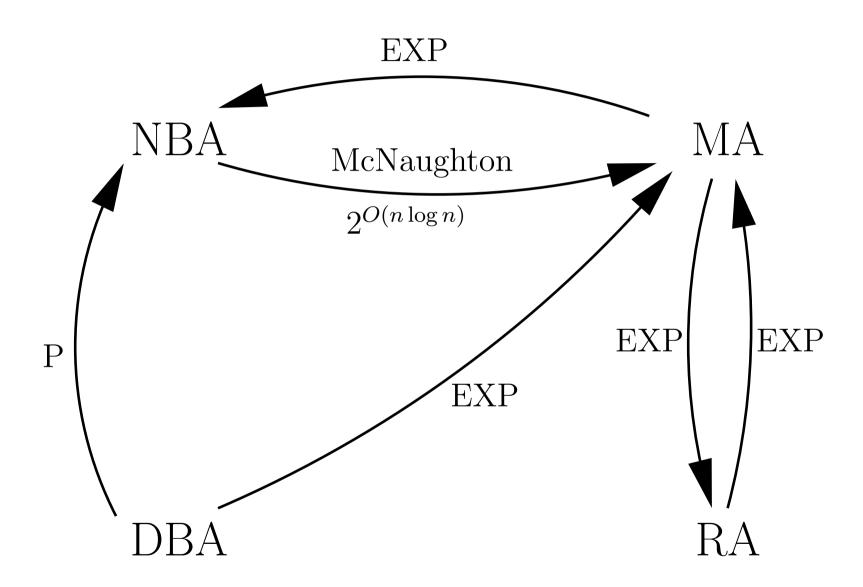

#### From Müller to Rabin

• 
$$T'(\langle S_1, \dots, S_k, s \rangle, a) = \langle S'_1, \dots, S'_k, s' \rangle$$
 where:  
 $-s' = T(s, a)$   
 $-S'_i = \emptyset$  if  $S_i = Q_i$ ,  $1 \le i \le k$   
 $-S'_i = (S_i \cup \{s'\}) \cap Q_i$ ,  $1 \le i \le k$ 

• 
$$P_i = \{ \langle S_1, \dots, S_i, \dots, S_k, s \rangle \mid S_i = Q_i \}, \ 1 \le i \le k$$

• 
$$N_i = \{ \langle S_1, \dots, S_i, \dots, S_k, s \rangle \mid s \notin Q_i \}, \ 1 \le i \le k$$

## The Big Picture

## **Exercises**

Write down Müller automata for the following languages:

1. 
$$\Sigma = \{a, b\}, L = (a + b)^* a^{\omega}$$

2. 
$$\Sigma = \{a, b, c\}, L = \{w \mid \text{if } a \text{ occurs infinitely often then } b \text{ occurs infinitely often in } w\}$$

Let  $A = \langle S, s_0, T, \{Q_1, \dots, Q_t\} \rangle$  be a Müller automaton. Consider the Rabin automaton  $A' = \langle S, s_0, T, \Omega \rangle$  where

$$\Omega = \{ (S \setminus Q_1, Q_1), \dots, (S \setminus Q_t, Q_t) \}$$

Give an example of A such that  $\mathcal{L}(A) \neq \mathcal{L}(A')$ .
