Terminology

Two-player games between Player 0 and 1 An infinite game $\langle G,\phi\rangle$ consists of

- \blacktriangleright a game graph G and
- a winning condition ϕ .

G defines the "playground", in which the two players compete. ϕ defines which plays are won by Player 0. If a play does not satisfy ϕ , then Player 1 wins on this play.

Game Graphs

- A game graph is a tuple $G = \langle S, S_0, T \rangle$ where:
 - S is a finite set of states,
 - ► $S_0 \subseteq S$ is the set of Player-0 states $(S_1 = S \setminus S_0 \text{ are the Player-1 states}),$
 - ▶ $T \subseteq S \times S$ is a transition relation. We assume that each state has at least one successor.

・ロト ・四ト ・ヨト ・ヨト 三国

Plays

A play is an infinite sequence of states $\rho = s_0 s_1 s_2 \cdots \in S^{\omega}$ such that for all $i \ge 0 \langle s_i, s_{i+1} \rangle \in T$.

It starts in s_0 and it is built up as follows:

If $s_i \in S_0$, then Player 0 chooses an edge starting in s_i , otherwise Player 1 picks such an edge.

Intuitively, a token is moved from state to state via edges: From S_0 -states Player 0 moves the token, from S_1 -states Player 1 moves the token.

Winning Condition

The winning condition describes the plays won by Player 0.

- A winning condition or winning objective ϕ is a subset of plays, i.e., $\phi \subseteq S^{\omega}$.
- We use logical conditions (e.g., LTL formulas) or automata theoretic acceptance conditions to describe ϕ .

Example:

- $\Box \diamondsuit s$ for some state $s \in S$
- ▶ All plays that stay within a safe region $F \subseteq S$ are in ϕ .
- ► Given a priority function p : S → {0, 1, ..., d}, all plays in which the smallest priority visited is even.

Games are named after their winning condition, e.g., Safety game, Reachability game, LTL game, Parity game,...

Types of Games

Given a play ρ , we define

•
$$\operatorname{Occ}(\rho) = \{s \in S \mid \exists i \ge 0 : s_i = s\}$$

• $\operatorname{Inf}(\rho) = \{s \in S \mid \forall i \ge 0 \exists j > i : s_j = s\}$

Given a set $F \subseteq S$,

Types of Games

 $\begin{array}{ll} \mbox{Given a priority function } p:S \to \{0,1,\ldots,d\} \mbox{ or an LTL formula } \varphi \\ \mbox{Weak-Parity Game} & \phi = \{\rho \in S^{\omega} \mid \min_{s \in {\rm Occ}(\rho)} p(s) \mbox{ is even}\} \\ \mbox{Parity Game} & \phi = \{\rho \in S^{\omega} \mid \min_{s \in {\rm Inf}(\rho)} p(s) \mbox{ is even}\} \\ \mbox{LTL Game} & \phi = \{\rho \in S^{\omega} \mid \rho \models \varphi\} \end{array}$

We will refer to the type of a game and give F, p, or φ instead of defining ϕ .

We will also talk about Muller and Rabin games.

A strategy for Player 0 from state s is a (partial) function

 $f: S^*S_0 \to S$

specifying for any sequence of states $s_0, s_1, \ldots s_k$ with $s_0 = s$ and $s_k \in S_0$ a successor state s_j such that $(s_k, s_j) \in T$. A play $\rho = s_0 s_1 \ldots$ is compatible with strategy f if for all $s_i \in S_0$ we have that $s_{i+1} = f(s_0 s_1 \ldots s_i)$. (Definitions for Player 1 are analogous.)

Given strategies f and g from s for Player 0 and 1, respectively. We denote by $G_{f,g}$ the (unique) play that is compatible with f and g.

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへで

Winning Strategies and Regions

Given a game (G, ϕ) with $G = (S, S_0, E)$, a strategy f for Player 0 from s is called a winning strategy if for all Player-1 strategies g from s, if $G_{f,g} \in \phi$ holds. Analogously, a Player-1 strategy g is winning if for all Player-0 strategies $f, G_{f,g} \notin \phi$ holds. Player 0 (resp. 1) wins from s if s/he has a winning strategy from s.

Winning Strategies and Regions

Given a game (G, ϕ) with $G = (S, S_0, E)$, a strategy f for Player 0 from s is called a winning strategy if for all Player-1 strategies g from s, if $G_{f,g} \in \phi$ holds. Analogously, a Player-1 strategy g is winning if for all Player-0 strategies f, $G_{f,g} \notin \phi$ holds. Player 0 (resp. 1) wins from s if s/he has a winning strategy from s. The winning regions of Player 0 and 1 are the sets

 $W_0 = \{ s \in S \mid \text{Player 0 wins from } s \}$

 $W_1 = \{ s \in S \mid \text{Player 1 wins from } s \}$

Note each state s belongs at most to W_0 or W_1 . Otherwise pick winning strategies f and g from s for Player 0 and 1, respectively, then $G_{f,g} \in \phi$ and $G_{f,g} \notin \phi$: Contradiction.

Questions About Games

Solve a game (G, ϕ) with $G = (S, S_0, T)$:

- 1. Decide for each state $s \in S$ if $s \in W_0$.
- 2. If yes, construct a suitable winning strategy from s.

Further interesting question:

▶ Optimize construction of winning strategy (e.g., time complexity)

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへで

▶ Optimize parameters of winning strategy (e.g., size of memory)

Example

Safety game (G, F) with $F = \{s_0, s_1, s_3, s_4\}$, i.e., $Occ(\rho) \subseteq F$ A winning strategy for Player 0 (from state s_0, s_3 , and s_4):

- From s_0 choose s_3 and from s_4 choose s_3
- A winning strategy for Player 1 (from state s_1 and s_2):
 - From s_1 choose s_2 , from s_2 choose s_4 , and from s_3 choose s_4

Example

Safety game (G, F) with $F = \{s_0, s_1, s_3, s_4\}$, i.e., $Occ(\rho) \subseteq F$ A winning strategy for Player 0 (from state s_0, s_3 , and s_4):

From s_0 choose s_3 and from s_4 choose s_3

A winning strategy for Player 1 (from state s_1 and s_2):

From s_1 choose s_2 , from s_2 choose s_4 , and from s_3 choose s_4 $W_0 = \{s_0, s_3, s_4\}, W_1 = \{s_1, s_2\}$

(日) (四) (코) (코) (코) (코)

Another Example

LTL game (G, φ) with $\varphi = \Diamond s_0 \land \Diamond s_4$ (visit s_0 and s_4) Winning strategy for Player 0 from s_0 :

From s_0 to s_3 , from s_3 to s_4 , and from s_4 to s_1 .

Note: this strategy is not winning from s_3 or s_4 . Winning strategy for Player 0 from s_3 :

From s₀ to s₃, from s₄ to s₃, and from s₃ to s₀ on first visit, otherwise to s₄.

Determinacy

Recall: the winning regions are disjoint, i.e., $W_0 \cap W_1 = \emptyset$ Question: Is every state winning for some player? A game (G, ϕ) with $G = (S, S_0, E)$ is called determined if $W_0 \cup W_1 = S$ holds.

Remarks:

1. We will show that all automata theoretic games we consider here are determined.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへで

2. There are games which are not determined (e.g., concurrent games: even/odd sum, paper-rock-scissors)

In general, a strategy is a function $f: S^+ \to S$. (Note that sometimes we might define f only partially.)

- 1. Computable or recursive strategies: f is computable
- 2. Finite-state strategies: f is computable with a finite-state automaton meaning that f has bounded information about the past (history).
- 3. Memoryless or positional strategies: f only depends on the current state of the game (no knowledge about history of play)

Positional Strategies

Given a game (G, ϕ) with $G = (S, S_0, E)$, a strategy $f : S^+ \to S$ is called positional or memoryless if for all words $w, w' \in S^+$ with $w = s_0 \dots s_n$ and $w' = s'_0 \dots s'_m$ such that $s_n = s'_m$, f(w) = f(w')holds.

A positional strategy for Player 0 is representable as

- 1. a function $f: S_0 \to S$
- a set of edges containing for every Player-0 state s exactly one edge starting in s (and for every Player-1 state s' all edges starting in s')

Finite-state Strategies

A strategy automaton over a game graph $G = (S, S_0, E)$ is a finite-state machine $A = (M, m_0, \delta, \lambda)$ (Mealy machine) with input and output alphabet S, where

- M is a finite set of states (called memory),
- $m_0 \in M$ is an initial state (the initial memory content),
- ▶ $\delta: M \times S \to M$ is a transition function (the memory update fct),
- ▶ $\lambda : M \times S \to S$ is a labeling function (called the choice function).

Finite-state Strategies

A strategy automaton over a game graph $G = (S, S_0, E)$ is a finite-state machine $A = (M, m_0, \delta, \lambda)$ (Mealy machine) with input and output alphabet S, where

- M is a finite set of states (called memory),
- $m_0 \in M$ is an initial state (the initial memory content),
- ▶ $\delta: M \times S \to M$ is a transition function (the memory update fct),
- $\lambda: M \times S \to S$ is a labeling function (called the choice function). The strategy for Player 0 computed by A is the function

$$f_A(s_0 \dots s_k) := \lambda(\delta(m_0, s_0 \dots s_{k-1}), s_k)$$
 with $s_k \in S_0$

and the usual extension of δ to words: $\delta(m_0, \epsilon) = m_0$ and $\delta(m_0, s_0 \dots s_k) = \delta(\delta(m_0, s_0 \dots s_{k-1}), s_k)$. Any strategy f, such that there exists an A with $f_A = f$, is called finite-state strategy.

Recall Example

Objective: visit s_0 and s_4 , i.e, $\{s_0, s_4\} \subseteq \operatorname{Occ}(\rho)$ Winning strategy for Player 0 from s_0 , s_3 and s_4 :

From s_0 to s_3 , from s_4 to s_3 , and from s_3 to s_0 on first visit, otherwise to s_4 .
